Evaluation Monitoring as an Approach to Assessing the Water Quality Impacts of Urban Stormwater Runoff Associated Constituents

In previous Newsletters reference has been made to Evaluation Monitoring as an alternative approach to conventional monitoring of urban area and highway stormwater runoff associated with assessing water quality impacts and the effectiveness of water quality management programs. Evaluation Monitoring evolved out of work that was done over the past four years by the author and his associates, principally Scott Taylor of RBF, Irvine, CA, in Orange County, California devoted to developing Best Management Practices (BMPs) for a new 26-mile toll road. Through work with the regulatory agencies and stakeholders on the water quality of potentially impacted waterbodies that would receive stormwater runoff from this toll road, it was possible to develop and implement an alternative approach to water quality monitoring/assessment.

It was known at the time of initiation of the Evaluation Monitoring Program that highway stormwater runoff contains chemical constituents and pathogen indicator organisms at concentrations that could cause violations of worst case based water quality standards at the point where this runoff enters receiving waters. The conventional approach for monitoring urban area and highway stormwater runoff involves collecting samples at the edge of the pavement, analyzing these samples for a suite of potential chemical pollutants and coliforms, and reporting the data to the regulatory agencies as part of filling the requirements for the NPDES stormwater permit. This approach is a compliance monitoring approach that evolved out of monitoring municipal and industrial wastewater effluents to determine if the effluent was complying with the NPDES permitted discharge limits.

The so-called water quality evaluation conducted as part of this type of compliance monitoring is based on determining whether the concentrations of the constituents in the runoff waters exceed the water quality standards that have been adopted to protect the designated beneficial uses of the waterbody receiving the runoff. It has become recognized that this type of monitoring provides a highly unreliable assessment of the potential water quality impacts of the constituents in the stormwater runoff. This end-of-pipe, edge-of-pavement monitoring has caused significant misunderstandings about impact of urban area and highway stormwater runoff associated constituents on the beneficial uses of receiving waters as a result of the fact that there are several heavy metals, organics, and other constituents in the runoff waters that are present at concentrations which exceed worst case based water quality criteria/standards. This exceedance

Proceedings of a conference, held in Mount Crested Butte, Colorado, August 7- 12, Sponsored by the Engineering Foundation.
